

- Equilibrium thermodynamics with capillary effect disagrees with the GCMC results for methane ethane mixture
- Simulation box size in confined & unconfined cases may mask or distort the critical point shift
- Increased box size decreases the time efficiency of simulation
- Wall-fluid interaction also affects the results of GCMC simulations
- These simulation parameters must be the reason why different approaches give different results
- Comparison to experimental results might be the solution to this problem

UNCONVENTIONAL RESERVOIR ENGINEERING PROJECT Advisory Board Meeting, November 3, 2017, Golden, Colorado 17
